Summary

In this paper, we present our scalable dynamic adaptive mesh refinement (AMR) library t8code, which was officially released in 2022 (Holke et al., 2022). t8code is written in C/C++, open source, and readily available at www.dlr-amr.github.io/t8code. It is developed and maintained at the Institute for Software Technology of the German Aerospace Center (DLR). The software library provides fast and memory efficient parallel algorithms for dynamic AMR to handle tasks such as mesh adaptation, load-balancing, ghost computation, feature search and more. t8code can manage meshes with over one trillion mesh elements (Holke et al., 2021) and scales up to one million parallel processes (Holke, 2018). It is intended to be used as mesh management backend in scientific and engineering simulation codes paving the way towards high-performance applications of the upcoming exascale era.

Statement of Need

Adaptive Mesh Refinement has been established as a successful approach for scientific and engineering simulations over the past decades (Babuvška & Rheinboldt, 1978; Bangerth et al., 2007; Dörfler, 1996; Teunissen & Keppens, 2019). By modifying the mesh resolution locally according to problem specific indicators, the computational power is efficiently concentrated where needed and the overall memory usage is reduced by orders of magnitude. However, managing adaptive meshes and associated data is a very challenging task, especially for parallel codes. Implementing fast and scalable AMR routines generally leads to a large development overhead motivating the need for external mesh management libraries like t8code.

Currently, t8code's AMR routines support a wide range of element types: vertices, lines, quadrilaterals, triangles, hexahedra, tetrahedra, prisms, and pyramids. The latter having a 1 : 10 refinement rule with tetrahedra emerging as child elements (Knapp, 2020). Additionally, implementation of other refinement patterns and element shapes is possible according to the specific requirements of the application. t8code aims to provide a comprehensive mesh management framework for a wide range of use cases in science and engineering applications.

Fundamental Concepts

t8code is based on the concept of tree-based adaptive mesh refinement. Starting point for the usage of t8code is an unstructured input mesh, which we denote a coarse mesh. This coarse

39 mesh describes the geometry of the computational domain. The coarse mesh elements are
40 refined recursively in a structured pattern, resulting in refinement trees of which we store only
41 minimal information of the finest elements (the leafs of the tree). We call this resulting fine
42 mesh the forest.

43 By enumerating the children in the refinement pattern we obtain a space-filling curve (SFC)
44 logic. Via these SFCs, all elements in a refinement tree are assigned an index and are stored in
45 linear order of these indices. Information such as coordinates or element neighbors do not need
46 to be stored explicitly but can be deduced from the index and the appropriate information
47 of the coarse mesh. The forest mesh can be distributed, that is, at any time, each parallel
48 process only stores a unique portion of the forest mesh, the boundaries of which are calculated
49 from the SFC indices; see [Figure 1](#).

50 While being successfully applied to quadrilateral and hexahedral meshes ([Burstedde et al.,](#)
51 [2011](#); [Weinzierl, 2019](#)), these SFC techniques are extended by t8code in a modular fashion,
52 such that arbitrary element shapes are supported. We achieve this modularity through a novel
53 decoupling approach that separates high-level (mesh global) algorithms from low-level (element
54 local) implementations. All high-level algorithms can be applied to different implementations
55 of element shapes and refinement patterns. A mix of different element shapes in the same
56 mesh is also supported.

Figure 1: Left: Quad-tree of an exemplary forest mesh consisting of two trees (k_0 , k_1) distributed over three parallel processes p_0 to p_2 . The SFC is represented by a black curve tracing only the finest elements (leafs) of each tree. Right: Sketch of the associated mixed shape mesh refined up to level three.

57 Performance

58 t8code supports distributed coarse meshes of arbitrary size and complexity, which we tested
59 for up to 370 million coarse mesh cells ([Burstedde & Holke, 2017](#)). Moreover, we present
60 some of our benchmark results from various performance studies conducted on the JUQUEEN
61 ([JUQUEEN Supercomputer, n.d.](#)) and the JUWELS ([JUWELS Supercomputer, n.d.](#)) super-
62 computers at the Jülich Supercomputing Center. t8code's ghost and partition routines are
63 exceptionally fast with proper scaling of up to 1.1 trillion mesh elements; see [Table 1](#), ([Holke](#)
64 [et al., 2021](#)). Furthermore, in a prototype code ([Dreyer, 2021](#)) implementing a high-order
65 discontinuous Galerkin method (DG) for advection-diffusion equations on dynamically adaptive
66 hexahedral meshes we observe a speed-up of 12 compared to non-AMR meshes with only an
67 overall 15% runtime contribution of t8code; see [Figure 2](#).

# Process	# Elements	# Elem. / process	Ghost	Partition
49,152	1,099,511,627,776	22,369,621	2.08 s	0.73 s
98,304	1,099,511,627,776	11,184,811	1.43 s	0.33 s

Table 1: Runtimes on JUQUEEN for the ghost layer and partitioning operations for a distributed mesh consisting of 1.1 trillion elements.

Figure 2: Runtimes on JUQUEEN of the different components of our DG prototype code coupled with t8code. Note that all features associated with dynamical mesh adaptation utilize only around 15% of the total runtime largely independent of the number of processes.

Conclusion

In this note, we introduce our open source AMR library t8code. We give a brief overview of the fundamental design principles and high-level operations. Due to the high modularity, t8code can be easily extended for a wide range of use cases. Performance results confirm that t8code is a solid choice for mesh management in high-performance applications in the upcoming exascale era.

Even though t8code is a newcomer to the market, it is already in use as the mesh management backend in various research projects, most notably in the earth system modeling (ESM) community. In the ADAPTEX project t8code is integrated with the Trixi framework (Schlottke-Lakemper et al., 2020) - a modern computational fluid dynamics code written in Julia. Over the next years several ESM applications are planned to couple to this combination, including MESSy, MPTrac, and SERGHEI. Moreover, t8code also plays an important role in several DLR funded projects, e.g., VISPLORE, HYTAZER, Greenstars and PADME-AM.

For further information beyond this short note and also for code examples, we refer to our Documentation and Wiki reachable via our homepage www.dlr-amr.github.io/t8code and our technical publications on t8code (Becker, 2021; Burstedde & Holke, 2016, 2017; Dreyer, 2021; Elsweijer, 2021; Fußbroich, 2023; Holke, 2018; Holke et al., 2021, 2022; Knapp, 2020; Lilikakis, 2022).
